Measurable Learning Objectives for Module 1:

A. Students will identify the phase of water found in each of various “bodies” of water

B. Students will explain how water transports (arrives and leaves) through various “bodies” of water and whether it is fueled by the sun and/or gravity

C. Students will draw and label pictures (modeling) that compare molecular distances in the three phases of water, including labeling that explains how energy from the sun affects molecular movement to fuel the phase changes

D. Students will draw and label a simple natural water cycle map (modeling) that includes all transport processes in the cycle

E. Students will explain how a drop of water moves through the natural water cycle on the map they created, including any relevant phase shifts the water goes through with each transport process in the water cycle

F. Students will create their own global travel maps of the natural water cycle (modeling) which accurately corresponds relevant water cycle transport processes to specific sites on the map (i.e., above ground, below ground, and at ground level)

    - All transport processes in the natural water cycle must be used at least once

    - Maps must include students’ own local drinking water source and drinking water sources on three other continents among the identified “bodies” of water on the map

    - When asked about specific stops on the map (minimum 3), students will explain the particular water cycle transport process indicated, including the water phase, how the water arrived at that stop on the map and how it is likely to leave
