Introduction:

Prior Knowledge:

Students must have a working understanding of all seven transport processes in the natural water cycle (i.e., evaporation, transpiration, condensation, precipitation, run-off, infiltration, and percolation) and how they work together.
Students must have a basic understanding of eutrophication, including sources that cause eutrophication and how eutrophication affects the organisms that live in and depend on the body of water.

Learning Goals:

- Learn about the human water cycle from drinking water source to the release of wastewater effluent back into the environment.
- Learn about the different types of drinking water sources (i.e., groundwater, surface water, and springs).
- Learn about the different types of wastewater treatment systems (i.e., centralized and decentralized systems).
- Learn about the infrastructure related to the movement of water and wastewater.
- Learn to gather and evaluate information/data/evidence.
- Learn to predict problems based on information/data/evidence.
- Learn to solve problems by gathering, evaluating, and synthesizing appropriate information/data/evidence into alternative solutions, and evaluating those alternate solutions to determine the most appropriate solution for the given circumstance.
- Learn to present their findings/results in a clear and coherent manner.
